Artwork/Project Description

This project started from a team discussion in one of my university courses. Our group brainstormed and found a common problem: creative students like us didn't have a single place to sell their work and also share their creative process. So, our team developed the idea for a website that combines a marketplace with a 'Creator Feed' for building a community. As the team's Web Developer, my main job was to turn our concept into a working prototype. I built the site using the Next.js framework and decided to use the browser's Local Storage for the database at first. This combination was a smart and fast way to build and test our core ideas, like the shopping cart, without a backend. Even though it was a group idea, I knew I had to plan the tech for the future. I designed the code so it could be easily upgraded to Firebase later to handle all the important features like user accounts, a live database, and image storage, preparing the site to scale up for more users.

Artwork/Project Description

For our next group project, my team decided to solve a problem we all experience at our own university, UC. We have a system called KP, or participation credits, that we need to collect from joining events, but the info was scattered everywhere, making it super hard to keep track. To prove this was a real issue, our team made a Google Form and surveyed other students, and the data confirmed our suspicions. That’s why we came up with Eventify. In this project, I took on two roles: UI/UX Designer and Software Developer. I started by designing the entire app flow and interface in Figma. Initially, our team built the app using Android Studio with Kotlin for the front end and Express.js for the back end. After that phase, I took the initiative to refine the project by rebuilding it with Flutter. I chose Flutter because it allows for a cross-platform app from one codebase, and I connected it to Firebase for a scalable and real-time database. This new stack makes the app more modern and much easier to maintain and grow in the future.

For our most in-depth project, ASLAN, my team tackled the challenge of learning difficult languages like Japanese, Chinese, and Korean. We found that learners struggle because resources are scattered, and no single app combines all the tools you need like flashcards, grammar, writing, and speaking practice. To solve this, and to contribute to the SDG goal of Quality Education, we designed ASLAN to be an all-in-one learning platform. As both the UI/UX Designer and a Software Developer on the team, I first designed the entire user journey and interface in Figma. Then, I worked on developing the front end natively using SwiftUI, which was a great experience. We chose Firebase as our backend solution for a very specific reason: to instantly save a user's progress when they finish a lesson. This was a key logical choice to help keep users motivated. Currently, the app focuses on providing a complete learning path for Korean, with our architecture designed to easily support the addition of Japanese, Chinese, and more languages in the future.

Artwork/Project Description

ENTEAM is a personal project I developed to solve a common challenge in team collaboration, where communication, task management, and project coordination are often scattered across different platforms. The application was designed as a centralized workspace where users can organize tasks, monitor project progress, and collaborate more effectively within a single web-based platform. I built ENTEAM using Next.js, TypeScript, and Tailwind CSS, focusing on responsive design, reusable components, and maintainable code. Through this project, I gained hands-on experience in developing modern web applications and designing interfaces that prioritize both usability and scalability.

Artwork/Project Description

CHESMA is a personal project I developed to help users manage household food inventory and reduce food waste by making better use of the ingredients they already have. The application allows users to track available ingredients and receive recipe recommendations based on the items currently in stock, making meal planning more practical and efficient. I built CHESMA using React, TypeScript, Vite, and Google Gemini API. Through this project, I gained hands-on experience in integrating AI APIs, handling user input, and developing responsive interfaces that provide dynamic and personalized recommendations.

MORE PROJECT TO COME!
